

/etc/apache2/sites-available/000-default.conf *

#<VirtualHost *:80>

The ServerName directive sets the request scheme, hostname and port that
the server uses to identify itself. This is used when creating
redirection URLs. In the context of virtual hosts, the ServerName
specifies what hostname must appear in the request's Host: header to
match this virtual host. For the default virtual host (this file) this
value is not decisive as it is used as a last resort host regardless.
However, you must set it for any further virtual host explicitly.
#ServerName www.example.com

ServerAdmin webmaster@localhost

DocumentRoot /var/www/html

Available loglevels: trace8, ..., trace1, debug, info, notice, warn,
error, crit, alert, emerg.
It is also possible to configure the loglevel for particular
modules, e.g.
#LogLevel info ssl:warn

ErrorLog \${APACHE_LOG_DIR}/error.log

CustomLog \${APACHE_LOG_DIR}/access.log combined

For most configuration files from conf-available/, which are
enabled or disabled at a global level, it is possible to
include a line for only one particular virtual host. For example the
following line enables the CGI configuration for this host only

```
# after it has been globally disabled with "a2disconf".

#Include conf-available/serve-cgi-bin.conf

#</VirtualHost>

# vim: syntax=apache ts=4 sw=4 sts=4 sr noet

<VirtualHost *:80>

    ServerAdmin webmaster@localhost

    DocumentRoot /var/www/html

    ProxyRequests Off

    <Proxy balancer://mycluster>

        BalancerMember http://localhost:8081

        BalancerMember http://localhost:8086

    </Proxy>

    ProxyPass / balancer://mycluster/

    ProxyPassReverse / balancer://mycluster/

    ErrorLog ${APACHE_LOG_DIR}/error.log

    CustomLog ${APACHE_LOG_DIR}/access.log combined

</VirtualHost>
```
